A rare presentation of idiopathic right subclavian artery aneurysm successfully tackled by endovascular stent-grafting

A 32-year-old woman presented with symptoms of dysphagia to solid food for 6 months. She had no significant past medical history or trauma. Examination revealed a subtly palpable pulsatile swelling at the root of right side of the neck. Contrast-enhanced CT showed a complex saccular aneurysm of the proximal right subclavian artery (figure 1A, B). The involved aneurysmal segment contained three separate saccules, the largest of which measured 4.7×2.3 cm. A selective digital subtraction angiography was done contemplating the possibility of endovascular intervention (figure 1C). In a cross-section image, the aneurysm is seen abutting the trachea which in turn compresses the oesophagus (figure 2A). Oesophago-gastroduodenoscopy was normal. Barium swallow showed smooth extrinsic compression of the oesophageal lumen at the level of aneurysm (figure 2B). An extensive aetiological work-up ruled out atherosclerosis, connective tissue disorders, vasculitis, infections, collagen disorders and congenital cardiovascular anomalies. She was taken up for endovascular stent-grafting and the aneurysm was successfully excluded using two stent-grafts (figure 3A, B). At follow-up, she has complete resolution of symptoms.

DISCUSSION

Subclavian artery aneurysm accounts for <0.2% of all aneurysms. Atherosclerosis, trauma, infections, vasculitis, connective tissue disorders and collagen vascular disease are causative for more than 95% of these.[1] Idiopathic subclavian aneurysms have very rarely been reported and most of them are considered congenital.[2]

The aneurysms are usually detected incidentally, but when symptomatic they commonly present as a pulsatile mass, neck pain, upper-limb ischaemia or mediastinal mass. Rare presentations that have been reported include dyspnoea, dysphagia and

haemoptysis.[3] Endovascular stent-grafting has been increasingly reported as a management option.
